Polynomial Regression

Multiple Regression

Polynomial Regression

- ▶ Simple linear regression: fit a line:

$$y_i \approx b_0 + b_1 x_i$$

- ▶ Polynomial regression: fit a polynomial:

$$y_i \approx b_0 + b_1 x_i + b_2 x_i^2 + b_3 x_i^3 + \cdots + b_{p-1} x_i^{p-1}$$

- ▶ The p coefficients b_0, b_1, \dots, b_{p-1} are estimated by minimizing the loss function below using the least squares principle:

$$S(b_0, \dots, b_{p-1}) = \sum_{i=1}^n (y_i - (b_0 + b_1 x_i + \cdots + b_{p-1} x_i^{p-1}))^2$$

- ▶ In practice, we make a computer find the coefficients for us. This class uses JMP 10, a statistical software tool.

Example: fly ash cylinders

- ▶ A researcher studied the compressive strength of concrete-like fly ash cylinders. The cylinders were made with varying amounts of ammonium phosphate as an additive.
- ▶ We want to investigate the relationship between the amount ammonium phosphate added and compressive strength.

Additive Concentrations and Compressive Strengths for Fly Ash Cylinders

x , Ammonium Phosphate (%)	y , Compressive Strength (psi)	x , Ammonium Phosphate (%)	y , Compressive Strength (psi)
0	1221	3	1609
0	1207	3	1627
0	1187	3	1642
1	1555	4	1451
1	1562	4	1472
1	1575	4	1465
2	1827	5	1321
2	1839	5	1289
2	1802	5	1292

Simple linear regression fit: $\hat{y}_i = 1498.4 - .6381x_i$

Regression

Multiple
Regression

x	y	\hat{y}	$e = y - \hat{y}$	x	y	\hat{y}	$e = y - \hat{y}$
0	1221	1498.4	-277.4	3	1609	1496.5	112.5
0	1207	1498.4	-291.4	3	1627	1496.5	130.5
0	1187	1498.4	-311.4	3	1642	1496.5	145.5
1	1555	1497.8	57.2	4	1451	1495.8	-44.8
1	1562	1497.8	64.2	4	1472	1495.8	-23.8
1	1575	1497.8	77.2	4	1465	1495.8	-30.8
2	1827	1497.2	329.8	5	1321	1495.2	-174.2
2	1839	1497.2	341.8	5	1289	1495.2	-206.2
2	1802	1497.2	304.8	5	1292	1495.2	-203.2

Quadratic fit: $\hat{y}_i = 1242.9 + 382.7x - 76.7x_i^2$

Regression Analysis

The regression equation is
 $y = 1243 + 383 x - 76.7 x^{**2}$

Predictor	Coef	StDev	T	P
Constant	1242.89	42.98	28.92	0.000
x	382.67	40.43	9.46	0.000
x**2	-76.661	7.762	-9.88	0.000

S = 82.14 R-Sq = 86.7% R-Sq(adj) = 84.9%

Analysis of Variance

Source	DF	SS	MS	F	P
Regression	2	658230	329115	48.78	0.000
Residual Error	15	101206	6747		
Total	17	759437			

Source	DF	Seq SS
x	1	21
x**2	1	658209

Quadratic fit: $\hat{y}_i = 1242.9 + 382.7x - 76.7x_i^2$

$$R^2 = 86.7\%$$

- ▶ The parabolic fit explained 86.7% of the variation in compressive strength.
- ▶ Note: for polynomial regression (and later, multiple regression) R^2 does not equal the squared correlation r_{xy} between x and y .
- ▶ Instead, $R^2 = r_{y\hat{y}}$:

$$r_{y\hat{y}} = \frac{\sum (y_i - \bar{y})(\hat{y}_i - \bar{\hat{y}})}{\sqrt{\sum (y_i - \bar{y})^2} \sqrt{\sum (\hat{y}_i - \bar{\hat{y}})^2}}$$

Cubic fit: $\hat{y}_i = 1188 + 633x - 214x^2 + 18.3x^3$

Regression Analysis

The regression equation is

$$y = 1188 + 633x - 214x^2 + 18.3x^3$$

Predictor	Coef	StDev	T	P
Constant	1188.05	28.79	41.27	0.000
x	633.11	55.91	11.32	0.000
x**2	-213.77	27.79	-7.69	0.000
x**3	18.281	3.649	5.01	0.000

S = 50.88

R-Sq = 95.2%

R-Sq(adj) = 94.2%

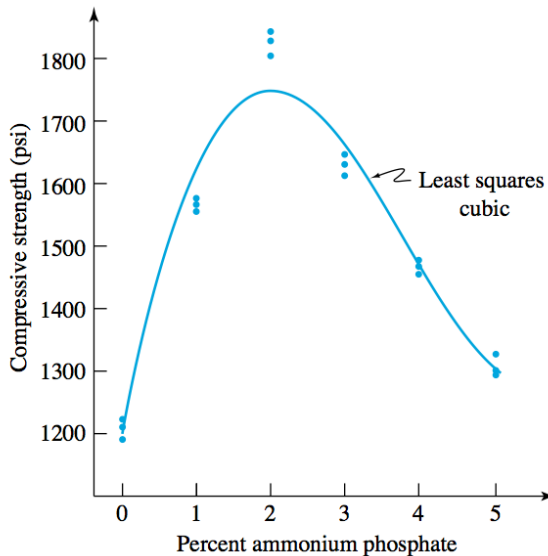

Analysis of Variance

Source	DF	SS	MS	F	P
Regression	3	723197	241066	93.13	0.000
Residual Error	14	36240	2589		
Total	17	759437			

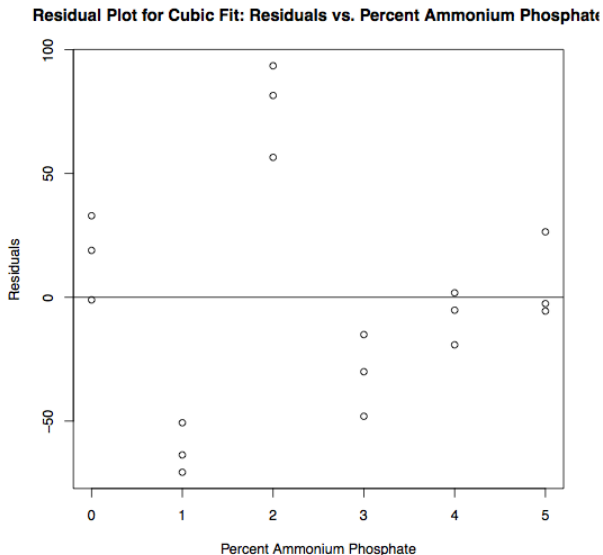

Polynomial
Regression

Multiple
Regression

Cubic fit: $\hat{y}_i = 1188 + 633x - 214x^2 + 18.3x^3$

R^2 rose to 95.2%, and the residual plot improved.

Multiple
Regression

Polynomial Regression

Multiple Regression

- **Multiple Regression:** regression on multiple variables:

$$y_i \approx b_0 + b_1x_{i,1} + b_2x_{i,2} + b_3x_{i,3} + \cdots + b_{p-1}x_{i,p-1}$$

- The p coefficients b_0, b_1, \dots, b_{p-1} are estimated by minimizing the loss function below using the least squares principle:

$$S(b_0, \dots, b_p) = \sum_{i=1}^n (y_i - (b_0 + b_1x_{i,1} + \cdots + b_{p-1}x_{i,p-1}))^2$$

- In practice, we make a computer find the coefficients for us. This class uses JMP 10.

Example: New York rivers data

- ▶ Nitrogen content is a measure of river pollution.

Variable	Definition
Y	Mean nitrogen concentration (mg/liter) based on samples taken at regular intervals during the spring, summer, and fall months
X_1	Agriculture: percentage of land area currently in agricultural use
X_2	Forest: percentage of forest land
X_3	Residential: percentage of land area in residential use
X_4	Commercial/Industrial: percentage of land area in either commercial or industrial use

- ▶ I will fit each of:

$$\hat{y}_i = b_0 + b_1 x_{i,1}$$

$$\hat{y}_i = b_0 + b_1 x_{i,1} + b_2 x_{i,2} + b_3 x_{i,3} + b_4 x_{i,4}$$

and evaluate fit quality.

Example: New York rivers data

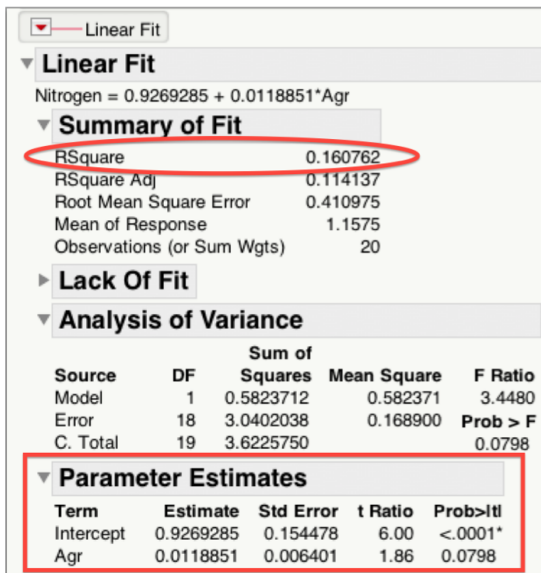

Row	River	Y	X_1	X_2	X_3	X_4
1	Olean	1.10	26	63	1.2	0.29
2	Cassadaga	1.01	29	57	0.7	0.09
3	Oatka	1.90	54	26	1.8	0.58
4	Neversink	1.00	2	84	1.9	1.98
5	Hackensack	1.99	3	27	29.4	3.11
6	Wappinger	1.42	19	61	3.4	0.56
7	Fishkill	2.04	16	60	5.6	1.11
8	Honeoye	1.65	40	43	1.3	0.24
9	Susquehanna	1.01	28	62	1.1	0.15
10	Chenango	1.21	26	60	0.9	0.23
11	Tioughnioga	1.33	26	53	0.9	0.18
12	West Canada	0.75	15	75	0.7	0.16
13	East Canada	0.73	6	84	0.5	0.12
14	Saranac	0.80	3	81	0.8	0.35
15	Ausable	0.76	2	89	0.7	0.35
16	Black	0.87	6	82	0.5	0.15
17	Schoharie	0.80	22	70	0.9	0.22
18	Raquette	0.87	4	75	0.4	0.18
19	Oswegatchie	0.66	21	56	0.5	0.13
20	Cohocton	1.25	40	49	1.1	0.13

$\hat{y}_i = b_0 + b_1x_{i,1}$: pollution vs. agricultural land.

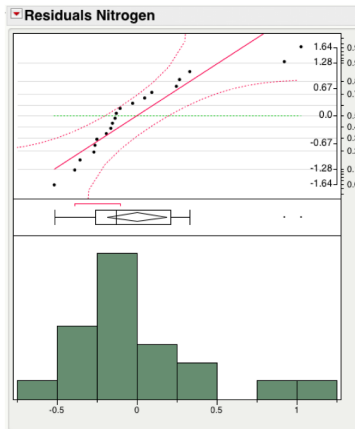

- It looks like the data could be roughly linear, although there are too few points to be sure.

$$\hat{y}_i = b_0 + b_1 x_{i,1}: \text{pollution vs. agricultural land.}$$

$$\hat{y}_i = b_0 + b_1 x_{i,1}: \text{pollution vs. agricultural land.}$$

Conclusions: $\hat{y}_i = b_0 + b_1x_{i,1}$

- ▶ A low R^2 means the model isn't very useful for predicting the pollution of other New York rivers outside our dataset.
- ▶ However, the lack of a pattern in the residual plot shows that the model is valid.
- ▶ The residuals depart from a bell shape slightly, but not enough to interfere with statistical inference.

$$\hat{y}_i = b_0 + b_1x_{i,1} + b_2x_{i,2} + b_3x_{i,3} + b_4x_{i,4}$$

Full model: observed pollution values vs fitted values

Describing
Relationships
Among Variables
(Ch. 4)

Dason Kurkiewicz

Polynomial
Regression

Multiple
Regression

Full model: residual plots

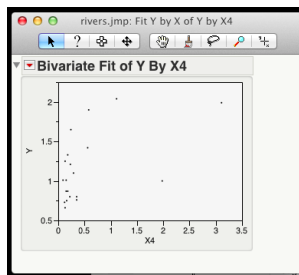

Conclusions: full model

- ▶ A higher R^2 indicates that the full model is more useful for predicting river pollution than the agriculture-only model.
- ▶ The residual plots show that the full model is valid too.

An even bigger model

- From the scatterplot of y on x_4 , it looks like x_4 needs at least a quadratic term.

- I can fit the model:

$$\hat{y}_i = b_0 + b_1x_{i,1} + b_2x_{i,2} + b_3x_{i,3} + b_4x_{i,4} + cx_{i,4}^2$$

which is a combination of polynomial regression and multiple regression.
